JBrowse

Mitch Skinner Ian Holmes Iab UC Berkeley

This talk

- How it works; why
- Progress since Toronto
- Walk through setting up browser

How it works (features)

Bio::DasI

(Bio::DB::GFF,

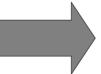

Bio::DB::SeqFeature::Store,

Etc)

Or

GFF file

script

JSON NCList

[24052,25621,1,"700","JYalpha"], [26993,32391,-1,"1035","CR32011"], [33775,46839,-1,"1408","CR32010"], [48155,51939,-1,"1823","CR32009"]

NCLists: Alekseyenko & Lee

Bioinformatics, 2007

Reasons to use pregenerated JSON

- No CGI needed for browsing
 - Easier installation
 - Scale to large genome, large number of users (zoom out to whole chromosome)
- Takes advantage of HTTP caching
 - web browser caches JSON data

Progress since Toronto

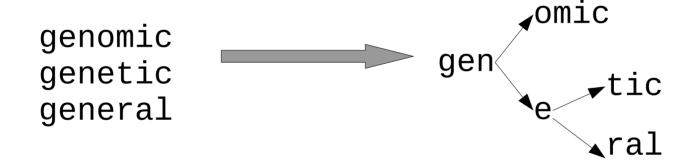

- Name/ID searching
- Quantitative (e.g., wiggle) tracks
- Subfeatures

Name/ID searching

- GBrowse: different search implementation for each data source
- JBrowse: we touch each feature anyway when we generate JSON, so just get names then
 - Afterward, collect name->location mappings into a trie

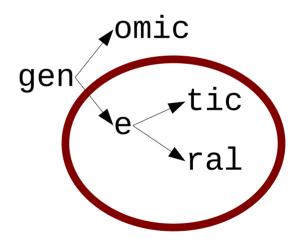

Name/ID searching: Trie

Shares prefixes among a set of strings

Name/ID searching: Trie

Subtries are lazily loaded

Quantitative Tracks

- ~12 min to generate tiles for Dmel conservation track (1 data point per base)
- Wiggle tiles compress well
 - ~5 bytes/base, half of which is filesystem overhead

Future

- Lots of things to do
- Question: What's most important to do next?

Thanks
